

Amendments to the Claims:

The following listing of claims will replace all prior versions, and listings, of claims in the application:

1. (Currently Amended) A logged-in device that is logged in by a plurality of specific devices via a predetermined communication path, said logged-in device comprising:

a response unit that gives a response of failed log-in to one specific device of interest, which has just output a request of log-in, when a number of specific devices that currently log in said logged-in device reaches a predetermined allowable number of simultaneous log-ins; and

a re-request timing specification unit that specifies a timing of re-request of log-in to determine a time when said specific device of interest, which has just output the request of log-in, should output another request of log-in, and assigns the specified timing of re-request to said specific device of interest, when said response unit gives the response of failed log-in, a predetermined relationship being between the specified timing and the specific device of interest.

2. (Original) A logged-in device in accordance with claim 1, wherein said re-request timing specification unit comprises:

a precedence designation unit that allocates an ordinal number of precedence to said specific device of interest, which has just output the request of log-in; and

a re-request timing determination unit that determines the timing of re-request of log-in with regard to said specific device of interest, based on the ordinal number of precedence allocated to said specific device of interest.

3. (Original) A logged-in device in accordance with claim 2, wherein said precedence designation unit allocates ordinal numbers of precedence to said plurality of specific devices in a sequence of outputting first requests of log-in.

4. (Original) A logged-in device in accordance with claim 2, wherein said re-request timing determination unit assigns a shorter timing of re-request of log-in to a specific device having a higher ordinal number of precedence.

5. (Original) A logged-in device in accordance with claim 1, wherein said re-request timing specification unit specifies the timing of re-request of log-in as a time constant that represents a time period to elapse before output of another request of log-in.

6. (Previously Presented) A logged-in device in accordance with claim 1, said logged-in device comprises at least one logical unit, which is independently logged in by each of said plurality of specific devices,

wherein said response unit gives a response of failed log-in with regard to a certain logical unit to one specific device of interest, which has just output a request of log-in to said certain logical unit, when a number of specific devices that currently log in said certain logical unit reaches an allowable number of simultaneous log-ins preset for said certain logical unit, and

said re-request timing specification unit specifies a timing of re-request of log-in to determine a time when said specific device of interest, which has just output the request of log-in to said certain logical unit, should output another request of log-in to said certain logical unit, and assigns the specified timing of re-request to said specific device of interest, when said response unit gives the response of failed log-in.

7. (Previously Presented) A logged-in device in accordance with claim 2, said logged-in device comprises at least one logical unit, which is independently logged in by each of said plurality of specific devices,

wherein said response unit gives a response of failed log-in with regard to a certain logical unit to one specific device of interest, which has just output a request of log-in to said certain logical unit, when a number of specific devices that currently log in said

certain logical unit reaches an allowable number of simultaneous log-ins preset for said certain logical unit, and

said re-request timing specification unit specifies a timing of re-request of log-in to determine a time when said specific device of interest, which has just output the request of log-in to said certain logical unit, should output another request of log-in to said certain logical unit, and assigns the specified timing of re-request to said specific device of interest, when said response unit gives the response of failed log-in.

8. (Original) A logged-in device in accordance with claim 1, wherein said plurality of specific devices are adjusted not to output the request of log-in simultaneously via said predetermined communication path.

9. (Original) A logged-in device in accordance with claim 2, wherein said plurality of specific devices are adjusted not to output the request of log-in simultaneously via said predetermined communication path.

10. (Original) A logged-in device in accordance with claim 1, wherein said predetermined communication path comprises an IEEE1394 bus.

11. (Original) A logged-in device in accordance with claim 2, wherein said predetermined communication path comprises an IEEE1394 bus.

12. (Original) A logged-in device in accordance with claim 1, said logged-in device communicating with said plurality of specific devices according to an SBP-2 protocol.

13. (Original) A logged-in device in accordance with claim 2, said logged-in device communicating with said plurality of specific devices according to an SBP-2 protocol.

14. (Currently Amended) A log-in device that logs into a specific device via a predetermined communication path, said log-in device comprising:

a log-in request unit that outputs a request of log-in to said specific device and, when receiving a response of failed log-in and a specified timing of re-request from said

specific device, outputs another request of log-in to said specific device at the specified timing of ~~re-request~~. re-request, a predetermined relationship being between the specified timing and the specific device.

15. (Original) A log-in device in accordance with claim 14, said log-in device being adjusted not to output the request of log-in simultaneously with output of a request of log-in from another device via said predetermined communication path.

16. (Original) A log-in device in accordance with claim 14, wherein said predetermined communication path comprises an IEEE1394 bus.

17. (Original) A log-in device in accordance with claim 14, said log-in device communicating with said specific device according to an SBP-2 protocol.

18. (Currently Amended) An inter-device communication system, where a logged-in device is logged in by a plurality of log-in devices via a predetermined communication path,

said logged-in device comprising:

a response unit that gives a response of failed log-in to one log-in device of interest, which has just output a request of log-in, when a number of log-in devices that currently log in said logged-in device reaches a predetermined allowable number of simultaneous log-ins; and

a re-request timing specification unit that specifies a timing of re-request of log-in to determine a time when said log-in device of interest, which has just output the request of log-in, should output another request of log-in, and assigns the specified timing of re-request to said log-in device of interest, when said response unit gives the response of failed log-in, a predetermined relationship being between the specified timing and the device of interest,

each of said plurality of log-in devices comprising:

a log-in request unit that outputs the request of log-in to said logged-in device and, when receiving the response of failed log-in and the specified timing of re-request from said logged-in device, outputs another request of log-in to said logged-in device at the specified timing of re-request.

19. (Currently Amended) A method of controlling log-in, so as to enable a plurality of log-in devices to log in at least one logical unit included in a logged-in device via a predetermined communication path, said method comprising the steps of:

(a) causing said logged-in device to give a response of failed log-in with regard to a certain logical unit to one log-in device of interest, which has just output a request of log-in to said certain logical unit, when a number of log-in devices that currently log in said certain logical unit reaches an allowable number of simultaneous log-ins preset for said certain logical unit;

(b) causing said logged-in device to specify a timing of re-request of log-in to determine a time when said log-in device of interest, which has just output the request of log-in to said certain logical unit, should output another request of log-in to said certain logical unit, and to assign the specified timing of re-request to said log-in device of interest, when the response of failed log-in is ~~given~~; given, a predetermined relationship between the specified timing and the log-in device of interest; and

(c) causing said log-in device of interest to output another request of log-in to said certain logical unit included in said logged-in device at the specified timing of re-request when said log-in device of interest receives the response of failed log-in with regard to said certain logical unit and the specified timing of re-request from said logged-in device.

20. (Original) A method in accordance with claim 19, wherein said step (b) comprises the step of:

causing said logged-in device to allocate ordinal numbers of precedence to said plurality of log-in devices in a sequence of outputting first requests of log-in to said certain logical unit, and to assign a shorter timing of re-request of log-in to a log-in device having a higher ordinal number of precedence.

21. (Currently Amended) A computer program product that causes a computer to carry out a series of logged-in processing, said computer being logged in by a plurality of specific devices via a predetermined communication path, said computer program product comprising:

a first program code that causes said computer to give a response of failed log-in to one specific device of interest, which has just output a request of log-in, when a number of specific devices that currently log in said logged-in device reaches a predetermined allowable number of simultaneous log-ins;

a second program code that causes said computer to specify a timing of re-request of log-in to determine a time when said specific device of interest, which has just output the request of log-in, should output another request of log-in, and to assign the specified timing of re-request to said specific device of interest, when the response of failed log-in is ~~given~~; given, a predetermined relationship being between the specified timing and the specific device of interest; and

a computer readable medium, in which said first program code and said second program code are stored.

22. (Original) A computer program product in accordance with claim 21, wherein said second program code comprises:

a program code that causes said computer to allocate ordinal numbers of precedence to said plurality of specific devices in a sequence of outputting first requests of

log-in, and to assign a shorter timing of re-request of log-in to a specific device having a higher ordinal number of precedence.

23. (Currently Amended) A computer program product that causes a computer to carry out a series of log-in processing, said computer logging in a specific device via a predetermined communication path, said computer program product comprising:

a program code that causes said computer to output a request of log-in to said specific device and, when receiving a response of failed log-in and a specified timing of re-request from said specific device, output another request of log-in to said specific device at the specified timing of ~~re-request; re-request~~, a predetermined relationship between the specified timing and the specific device; and

a computer readable medium, in which said program code is stored.

24. (Currently Amended) A data signal embodied in a carrier, said data signal representing a computer program that causes a computer to carry out a series of logged-in processing, said computer being logged in by a plurality of specific devices via a predetermined communication path, said data signal comprising:

a first program code that causes said computer to give a response of failed log-in to one specific device of interest, which has just output a request of log-in, when a number of specific devices that currently log in said logged-in device reaches a predetermined allowable number of simultaneous log-ins; and

a second program code that causes said computer to specify a timing of re-request of log-in to determine a time when said specific device of interest, which has just output the request of log-in, should output another request of log-in, and to assign the specified timing of re-request to said specific device of interest, when the response of failed log-in is given, a predetermined relationship between the specified timing and the specific device of interest.

25. (Original) A data signal in accordance with claim 24, wherein said second program code comprises:

a program code that causes said computer to allocate ordinal numbers of precedence to said plurality of specific devices in a sequence of outputting first requests of log-in, and to assign a shorter timing of re-request of log-in to a specific device having a higher ordinal number of precedence.

26. (Currently Amended) A data signal embodied in a carrier, said data signal representing a computer program that causes a computer to carry out a series of log-in processing, said computer logging in a specific device via a predetermined communication path, said data signal comprising:

a program code that causes said computer to output a request of log-in to said specific device and, when receiving a response of failed log-in and a specification of a timing of re-request from said specific device, output another request of log-in to said specific device at the specified timing of re-request, a predetermined relationship being between the specified timing and the specific device.

27. (Currently Amended) A computer program that causes a computer to carry out a series of logged-in processing, said computer being logged in by a plurality of specific devices via a predetermined communication path, said computer program comprising:

a first program code that causes said computer to give a response of failed log-in to one specific device of interest, which has just output a request of log-in, when a number of specific devices that currently log in said logged-in device reaches a predetermined allowable number of simultaneous log-ins; and

a second program code that causes said computer to specify a timing of re-request of log-in to determine a time when said specific device of interest, which has just output the request of log-in, should output another request of log-in, and to assign the

specified timing of re-request to said specific device of interest, when the response of failed log-in is given, a predetermined relationship being between the specified timing and the specific device of interest.

28. (Original) A computer program in accordance with claim 27, wherein said second program code comprises:

a program code that causes said computer to allocate ordinal numbers of precedence to said plurality of specific devices in a sequence of outputting first requests of log-in, and to assign a shorter timing of re-request of log-in to a specific device having a higher ordinal number of precedence.

29. (Currently Amended) A computer program that causes a computer to carry out a series of log-in processing, said computer logging in a specific device via a predetermined communication path, said computer program comprising:

a program code that causes said computer to output a request of log-in to said specific device and, when receiving a response of failed log-in and a specified timing of re-request from said specific device, output another request of log-in to said specific device at the specified timing of re-request, a predetermined relationship being between the specified timing and the specific device.
